Non-Decimal Units for LATEX

Mikkel Eide Eriksen mikkel.eriksen@gmail.com

October 4, 2020

1 Preface

Many historical unit systems were non-decimal. For example, the Danish rigsdaler 1 — where 1 rigsdaler consists of 6 mark, each again consisting of 16 skilling for a total of 96 skilling or per rigsdaler — was used from 1625 to 1875, when currency was decimalised to the current system of 1 krone = 100 øre.

Units for such measures as length, area, weight, and so on were also often non-decimal, and in fact remain so in the few places of the world that have not made the change to the metric system.

The non-decimal numbers were chosen due to their high number of division factors, which simplified mental arithmetic — eg. when sharing an amount of money or dividing goods.

This package enables creation and configuration of such units to facilitate their presentation in textual and tabular contexts, as well as simple summing.

In order to do this, values are divided into segments, separated by decimal points: The historical Danish monetary value 1 Rdl. 2 $\mbox{\ensuremath{\not\sim}}$ 3 $\mbox{\ensuremath{\beta}}$ is entered as 1.2.3, which the code then formats it appropriately.

 $^{^{1} \}verb|https://en.wikipedia.org/wiki/Danish_rigsdaler|$

2 Configuration

The package is configured in the following manner:

```
\usepackage[\langle options \rangle] \{ non-decimal-units \}
```

Where $\langle options \rangle$ may contain one or more of the following unit systems. See page 14 for details.

```
british Currencies
danish Currencies and areas
german Currencies
```

Alternately, one may configure new units via \nduNewUnit \rightarrow P.10.

$\label{local_noise} \label{local_noise} $$ \continuous (\continuous) $$$

Can be used to set global or local options. See further documentation for possible keys.

3 Usage

3.1 Formatting Values

Formats $\langle value \rangle$ according to the setup configured for the $\langle unit name \rangle$, as well as any provided $\langle options \rangle$. The number of decimal points and the values between them determine how many and which segments are displayed.

Empty segments are skipped.

```
Example usage: \nduFormatValue macro
\nduFormatValue{danish rigsdaler}{1.2.3}\\
\nduFormatValue{danish rigsdaler}{1..}\\
\nduFormatValue{danish rigsdaler}{2.}\\
\nduFormatValue{danish rigsdaler}{3.3}\\

1 Rdl. 2 & 3 &
1 Rdl.
2 & 3 &
```

3.1.1 Options

```
show=values
show=values and symbols
                                            (initially values and symbols)
show=symbols
       Changes which information is included in the expansion.
       Because only those segments with a value will be included,
       show=symbols can be used to list the segment units (though if only
       one or two is needed, it may be preferable to use \nduSymbol \to P.10).
           \nduFormatValue{danish hartkorn}
             [show=symbols]
             {0.0.0.0.0}
           \nduFormatValue{danish hartkorn}
             [show=symbols]
             {0.0...}
          Td. Skp. Fjk. Alb. Pg.
          Td. Skp.
```

See also section 4 for further discussion on possible options.

3.2 Tabular Data

In order to align values in a tabular context, the \nduAlignedHeader and \nduAlignedValue macros wrap each segment in a \makebox of equal width.

All segments will be included in the headers and cells, whether they contain a value or not. If no value is provided for the segment and no nil replacement is specified with the replace nil with P.7 key, the box will be empty.

Formats the unit symbols in boxes suitable for a header. See page 10 for configuration of symbols.

See $\mbox{\em NduFormatValue}^{\to P.3}$ for possible arguments.

```
Example usage: \nduAlignedHeader and \nduAlignedValue macros
```

```
\begin{tabular}{r r}
```

\toprule

- & \d \nduAlignedHeader{danish rigsdaler} \\ \midrule
- a & $\nduAlignedValue\{danish\ rigsdaler\}\{1.2.3\}\ \$
- b & \nduAlignedValue{danish rigsdaler}{100..} \\
- c & \del{c} \nduAlignedValue{danish rigsdaler}{.1.} \\bottomrule

(DOCCOUNTATE

\end{tabular}

	Rdl.	≯	ß
a	1	2	3
b	100		
c		1	

3.2.1 Options

```
aligned value width=\langle length \rangle
                                                                (initially 5em)
       Changes the width of each segment.
           Example usage: aligned value width key
           \begingroup
           \ne
             aligned value width=3em,
           \verb|\begin{tabular}{r r}|
             \toprule
             & \nduAlignedHeader{danish rigsdaler} \\
             a & \nduAlignedValue{danish rigsdaler}{1.2.3} \\
             b & \nduAlignedValue{danish rigsdaler}{100..} \\
             c & \nduAlignedValue{danish rigsdaler}{.1.} \\
             \bottomrule
           \end{tabular}
           \endgroup
                  Rdl.
                    1
                   100
            b
            \mathbf{c}
```

```
replace nil with=\langle...\rangle (no default, initially empty)
treat zero as nil (initially not set)
```

The key replace nil with replaces nil (empty) segments with a custom string.

The key treat zero as nil replaces 0 with nothing, which in turn means that setting both will replace both zero and nil with the custom string.

	Rdl.	*	ß
a	1	2	3
b	100	_	_
\mathbf{c}	_	1	_

3.3 Arithmetical Operations

Basic arithmetic functions can be used to build a result for display. Internally, this is done by converting the value to a representation, which is the total number of the smallest usable unit, eg. 1 Rdl. 2 $\mbox{\ensuremath{\upmu}}$ 3 $\mbox{\ensuremath{\upmu}}$ is 131 skilling.

Results can be gathered in two ways, either manually via the \nduMath macro, or automatically via the sum to key, the latter being especially suitable in tabular contexts.

The arguments of \ndots are identical to those of the \ndots dufformatValue^{\rightarrow P.3} macro, except for the addition of the \ndots argument, under which the result will be accumulated. It does not expand to any output. The first time a result name is used, it is assumed that the value is 0.

The \nduFormatResult macro takes the $\langle result\ name \rangle$ and formats it for display in the same way as \nduFormatValue $^{\rightarrow P.3}$.

Likewise, \nduAlignedResult macro formats a result in the same way as $\nduAlignedValue^{\rightarrow P.5}$.

All three may be further configured via the $\langle options \rangle$ in the same way as the regular macros.

```
Example usage: \nduMath and \nduFormatResult macros
\nduMath{danish rigsdaler}{example 1}{+}{0.0.10}
\nduMath{danish rigsdaler}{example 1}{+}{0.2}
\nduMath{danish rigsdaler}{example 1}{+}{0.2}
\nduMath{danish rigsdaler}{example 1}{+}{0.5.1}
\nduFormatResult{danish rigsdaler}{example 1} % = 1.2.3

1 Rdl. 2 & 3 &
```

```
Example usage: \nduAlignedResult macro
\nduAlignedHeader{danish rigsdaler}\\
\nduAlignedResult{danish rigsdaler}{example 1}

Rdl. & $\beta$
1 2 3
```

3.3.1 Options

```
sum to = \langle name \rangle (initially empty)
```

Setting this key will cause all uses of $\$ and $\$ and $\$ in the current group to be summed under the given name.

```
Example usage: sum to key
\begingroup
\nduset{
  aligned value width=3em,
 replace nil with=---,
  sum to=example 2
\begin{tabular}{r r}
  \toprule
  & \nduAlignedHeader{danish rigsdaler} \\
  \midrule
  a & \nduAlignedValue{danish rigsdaler}{1.2.3} \\
  b & \nduAlignedValue{danish rigsdaler}{100.1.} \\
  \bottomrule
  total & \nduAlignedResult{danish rigsdaler}{example 2} \\ % = 101.3.3
\end{tabular}
\endgroup
         Rdl.
    b
          100
          101
                 3
 total
```

Results are global and remain accessible outside the group:

```
\nduFormatResult{danish rigsdaler}{example 2}
101 Rdl. 3 & 3 ß
```

Adding an additional 15 skilling to the existing result gives:

```
\nduMath{danish rigsdaler}{example 2}{+}{0.0.15}
\nduFormatResult{danish rigsdaler}{example 2} % = 101.4.2
101 Rdl. 4 & 2 &
```

3.4 Accessing Information About Units

Expands to the name of the the given segment of the unit. Set by segment $\langle n \rangle / \text{name}^{\rightarrow P.12}$.

$\label{local_norm} $$\operatorname{\down}(\operatorname{\down$

Expands to the symbol of the the given segment of the unit. Set by segment $\langle n \rangle$ /symbol^{\rightarrow P.12}.

Expands to the conversion factor of the the given segment of the unit, ie. how many of the underlying segment the given segment consists of.

That is, 1 \nduName{danish rigsdaler}{0} consists of \nduFactor{danish rigsdaler}{0} \nduName{danish rigsdaler}{1}.

That is, 1 rigsdaler consists of 6 mark.

4 Creating New Units

If the included units are not suitable, more can be created. Pull requests are also welcome at https://github.com/mikkelee/latex-units.

$\label{local_norm_local_norm_local} \del{local_norm_l$

Units can have up to 5 segments, numbered $\langle 0-4 \rangle$. The left-most segment, that is, the *top* or *root* segment, is numbered 0.

The numeral part of the below key paths **segment 0**/ can be any integer up to 4, ie. **segment 4**/. The internal number of segments is determined by how many name keys are created.

See below for available settings.

It is possible to create shortcut macros for commonly used $\langle unit name \rangle$ s with optional overriding options.

These macros take the same arguments as the full $\nduFormatValue^{\rightarrow P.3}$ macro, except without the first argument (ie. the name of the unit).

```
\nduNewMacro{danish rigsdaler}
[segment 0/symbol={R\textsuperscript{dl}}]
{myRdl}
\myRdl{1.2.3}
```

$\nduCommonSymbols{\langle key/value\ pairs \rangle}$

It is possible to configure commonly used symbols using the form $\langle name \rangle = \langle symbol \rangle$. These will be used as fallbacks if no specific symbol is configured for a segment via segment $\langle n \rangle / \text{symbol}^{\to P.12}$.

4.0.1 Options

```
When displaying a value, this string will be inserted between each segment.

\[
\text{NduFormatValue{danish hartkorn}[} \]
\text{show=values,} \]
\text{segment separator=.} \]
\[
\{1.2.3.4\} \]
\text{NduFormatValue{danish rigsdaler}} \]
\[
\{\text{[segment separator={---}]} \}
\{1.2.3\}
\]
\[
\text{1.2.3.4} \]
\[
\text{1.2
```

```
restrict segment depth=(integer) (initially no restriction)
```

When calculating or displaying a value, only the segments up to and including $\langle integer \rangle$ will be considered.

In this document, the depth has been globally set to 2 for danish rigsdaler, but the older historical sub-unit penning can be included by locally setting the depth to 3 (or indeed not restricting it globally).

```
\nduFormatValue{danish rigsdaler}
[restrict segment depth=3]
{1.2.3.4}
1 Rdl. 2 & 3 & 4 &
```

```
segment \langle n \rangle/name=\langle name \rangle (no default, initially undefined)
```

Gives the proper name of the segment's unit. Used internally to determine how many segments the unit contains. Can be accessed with by \ne 'P. 10.

```
segment \langle n \rangle/symbol=\langle symbol \rangle (no default, initially undefined)
```

Configures a symbol displaying the unit. This is used in \nduAlignedHeader and is also available via \nduSym when defining the segment $\langle n \rangle$ /display (see below).

If none is configured, an attempt to look up a common symbol by its name is made. These can be configured with $\dot{NduCommonSymbols}^{P.11}$.

When displaying a value, the segments will be wrapped between the $\langle prefix \rangle$ and $\langle suffix \rangle$.

The macro \nduSym is available here to show the symbol configured for the segment.

The default is to use the symbol as prefix, but can be overriden if necessary.

```
segment \langle n \rangle / factor = \langle integer \rangle  (no default, initially undefined)
```

The conversion factor of a segment is how many of the underlying segment the given segment consists of.

This is used in the math macros, in order to calculate the correct segment values.

Can be accessed via $\nduFactor^{\rightarrow P.10}$.

These keys can of course also be set temporarily in $\mbox{\tt nduFormatValue}^{\to P.3}$

```
\nduFormatValue{danish rigsdaler}
  [segment 1/symbol=Mk.]
  {.9.}

\nduFormatValue{danish rigsdaler}
  [segment 0/display={}{ Rigsdaler og}]
  {1.2.3}

\nduFormatValue{danish rigsdaler}[
    segment separator={---},
    segment 0/display={(}{)},
    segment 1/display={[}{]},
    segment 2/display={\{}{\}},
  ]
  {1.2.3}

9 Mk.
1 Rigsdaler og 2 \(\frac{1}{2}\) 3 \(\frac{1}{2}\)
(1)—[2]—{3}
```

```
create macro named=\(control sequence\) (no default, initially empty)
```

Units may provide a default shortcut macro, for example the danish rigsdaler unit configures \rdl.

This is done via $\mbox{\normalfont{$\backslash$}}$ which describes the arguments of the resulting macros.

```
\rd1{2.3.}
```

5 Included Units

On the following pages are the units included with the package.
